Structure and DNA sequence of Insert and Flanking genomic region of Potato Event EH92-527-1

Summary

The purpose of the investigation presented was to determine and disclose the structure and DNA sequence of the insert including flanking potato chromosomal DNA sequence in potato event EH92-527-1. Using chromosome walking and PCR it was shown that the insert had the structure of an inverted repeat in a tail-to-tail arrangement with two right border regions as junctions to the potato chromosomal DNA. At the tail-to-tail fusion a short DNA sequence is found, which is present on opposite strands in two regions of the *gbss* antisense fragment of transformation vector pHoxwG as two patches of microhomology. Upon integration a minor DNA segment (27 bp) at the right T-DNA border was deleted. The structural rearrangement at the left border region led to the deletion of a fragment containing the T-DNA left border repeat and the nopaline synthase polyadenylation sequence connected to the *gbss* antisense gene fragment. No DNA sequences other than T-DNA were found within the tail-to-tail fusion insert. The inverted repeat extends into potato chromosomal DNA, thus the flanking DNA sequence on both sides of the insert were the same. The complete DNA sequence of the insert together with 2156 bp of potato flanking sequence is presented. Southern blot analysis results were consistent with the inverted repeat region extending into potato chromosomal DNA.

The structure of the insert in potato line EH92-527-1 including the same potato chromosomal DNA being present on either side of the insert is consistent with being the result of a DNA repair process occurring upon integration of the T-DNA of transformation vector pHoxwG.

Genomic DNA isolated in 1998 and 2005 showed the same hybridization patterns upon Southern blot analysis for four different restriction enzyme combinations, providing evidence for the genetic stability of the insert structure over multiple generations of clonally propagated EH92-527-1.

Introduction

Potatoes have been modified for altered starch content so that the ratio of amylopectin to amylose produced in the potato has been altered to a level of > 98 % amylopectin. This amylopectin starch is desirable for its properties in industrial applications. Potato variety Prevalent, was transformed via *Agrobacterium* with an antisense *gbss* (granule bound starch synthase) gene that caused reduced expression of a granule bound starch synthase gene. The potato transformant that gave rise to the genetically modified (GM) clone analyzed here, designated EH92-527-1, was transformed with the plasmid pHoxwG containing, within the T-DNA borders the *gbss* antisense gene under the control of the potato *gbss* promoter and the *nptII* (neomycin

phosphotransferase II) gene under control of the *nos* (nopaline synthase) promoter. The purpose of this study was to determine the structure and DNA sequence of the insert and the DNA sequence of the flanking potato genomic region.

Materials and Methods

DNA isolation

Total DNA was isolated from potato leaves according to Nucleon PhytoPure (Amersham Biosciences, Piscataway, NJ USA). Total DNA noted as isolated in 1998 was isolated according to Haymes (1996).

Amplification of insert related DNA fragments

Internal structures of the insert in event EH92-527-1 were amplified and cloned using Advantage™ Genomic PCR Kit (Clontech, Palo Alto, CA USA) and Advantage™ PCR Cloning Kit (Clontech). Specific primers used for amplification of fragments containing insert sequence are listed.

Primer name	Primer sequence
Kom2.1	5'TCCCTTAGCAGAAGGCAACTG3'
Kom2.2	5'CAAAAATGCTCCACTGACGTTTC3'
Kom6.1	5'AGACCTCCAACCTTTGAAGCTC3'
Kom6.2	5'GTTAGCTCACTCATTAGGCACC3'
Kom15	5'GATGTTTCGCTTGGTGGTC3'
Kom16	5'GGAAGTACAGAACCGCAAC3'

Internal fragments of the insert were amplified in the reaction setup:

BD Advantage Biosciences, Clontech

1 µl gDNA 527-1 (250 ng)
5 µl BD Advantage 2 PCR Buffer
1 µl of each primer (25mM)
1 µl 50X dNTP Mix
1 µl BD Advantage 2 Polymerase Mix
ddH₂O to a total volume of 50 µl

Amplifications were performed in an Eppendorf Mastercycler:

Isolation of EH92-527-1 insert and determination of flanking sequence.

In order to clarify the structure of the insert and extend the analysis of DNA sequences into the potato genome, reactions using GenomeWalker™ were performed.

GenomeWalker™ libraries for the purpose of isolating DNA sequence associated with the insert of event EH-92-527-1 were produced by the digestion of genomic DNA with restriction enzymes yielding blunt ended DNA fragments and the subsequent ligation of adaptor fragments to the generated blunt ended genomic fragments. The structure of the produced libraries can be utilized to amplify fragments of partly unknown DNA sequence by PCR. In a first PCR reaction, one primer is specific for known DNA sequence while the second primer is targeting the adaptor fragment DNA sequence ligated to the genomic DNA. In a second PCR reaction, a nested specific primer targeting known sequence is used together with a nested adaptor primer targeting the adaptor DNA sequence. The second PCR step is performed in order to increase the probability of intended fragments being amplified. Several libraries, using different restriction enzymes, are produced to ensure that fragments can be produced by PCR at least from some library, which is dependent on organism and local genome specific restriction patterns.

Internal structures and junctions between the insert and potato chromosomal DNA were amplified and cloned using Universal GenomeWalker™ Kit (Clontech), Advantage™ Genomic PCR Kit (Clontech) and Advantage™ PCR Cloning Kit (Clontech). Libraries were made of total DNA from EH92-527-1 for the Universal GenomeWalker™ Kit using the restriction enzymes *DraI*, *EcoRV*, *HpaI*, *MscI*, *PvuII*, *Scal* and *StuI* (New England Biolabs, Beverly MA, USA). The approach used in the GenomeWalker™ kit provides the basis for walking upstream or downstream in a genomic DNA from a known DNA sequence (Siebert et al. 1995a; Siebert et al. 1995b).

Specific primers, primary as well as nested, used for amplification of fragments containing internal structures as well as junctions to chromosomal DNA are listed.

Reactions were performed as described in the protocols for Universal GenomeWalker™ Kit (Clontech) and Advantage™ Genomic PCR Kit (Clontech).

DNA sequencing was performed on a service basis by MWG-Biotech, www.mwg-biotech.com

Individual sequences were assembled using ContigExpress of the Vector NTI suite, Informax, www.invitrogen.com.

Southern blot analysis

Southern blot analysis was used to verify the structure of inserted DNA in EH92-527-1 and to determine stability of the insert over time. Genomic DNA was isolated from leaf tissue of EH92-527-1 and parental variety Prevalent.

For investigation of the insert, 10 µg of isolated DNA was digested with *EcoRI*, *EcoRV*, *MscI*, *HindIII*, *BspHI*, *MfeI* and *HpaI*, in single reactions or in different combinations of the enzymes (New England Biolabs), and separated by gel electrophoresis for 2 to 3 hours. The DNA was transferred onto membranes (Hybond N+, Amersham Biosciences), and hybridized with different probes of the T-DNA of pHoxwG (*nptII*, *gbss* promoter, part of *gbss* antisense fragment or *nos* promoter, *Figure 4*) using DIG Easy Hyb and PCR DIG Probe Synthesis kit (Roche Applied Science). The following wash, block and detection steps were made with solutions and buffers from DIG Wash and Block buffer set and DIG DNA Labeling and Detection kit (Roche Applied Science) according to the manufacturer's instructions. The membranes were exposed to Hyperfilm-ECL (Amersham Biosciences). Molecular markers used were DNA Molecular Weight Marker II, DIG-labeled and DNA Molecular Weight Marker III, DIG-labeled (Roche Applied Science).

Results

Amplification of insert related DNA fragments

Internal insert DNA fragments were amplified using the T-DNA sequence of pHoxwG as a guide as shown in *Figure 1*. Primer combinations KOM2.1-KOM2.2, KOM6.1-KOM6.2 and KOM15-KOM16 all yielded fragments of the expected size upon amplification of genomic DNA isolated from potato event EH92-527-1. The DNA sequences of the isolated fragments were consistent with transformation vector pHoxwG in the regions amplified. Attempts to amplify fragments towards the left border region were unsuccessful (data not shown).

Seven genomic libraries were constructed in the Universal GenomeWalker™ format using DNA isolated from event EH92-527-1, which was restriction digested with *DraI*, *EcoRV*, *HpaI*, *MscI*, *PvuII*, *ScaI* and *StuI*. Primer KOM8 and nested primer KOM9 were used to amplify a fragment which contained one partial *gbss* antisense DNA segment and an inverted *gbss* DNA segment. At the site of inversion a short DNA sequence was found that is present on opposite strands in two regions of the *gbss* antisense fragment of transformation vector pHoxwG as two patches of microhomology that are shown in *Figure 2*. Further primers were designed for targeting and amplifying unknown DNA sequence distal to the *gbss* fragment found as an inversion. Primer KOM28 and nested primer KOM29 were used to generate a 1909 bp fragment from the *HpaI* library, which contained the previously known inversion but further extending until the start of the *gbss* antisense segment and 3' DNA sequence of the *gbss* promoter. This shows that in addition to the inversion there is inverted repeated DNA sequence contained in the insert, since the 5' end of the *gbss* antisense segment as well as the *gbss* promoter already had been determined as constituents of the insert upstream of the amplified fragment using the nested KOM29 primer.

Two further primer pairs were designed that targeted the inversion and could thus only amplify DNA sequence downstream of known T-DNA sequence. Primer LB1 and nested primer LB2 yielded two different fragments of 1391 bp and 2503 bp upon amplification of the *EcoRV* library, which showed that the inverted repeat structure extended beyond the start of the *gbss* promoter. Primer KOM30 and nested primer KOM31 were used to amplify one fragment each from the *EcoRV*, *MscI* and *PvuII* libraries, all containing DNA sequence that provided evidence for an inverted repeat structure of the insert. All fragments, amplified by three different specific primers and determined to contain DNA sequence originating from the insert, were consistent with that the insert contain an inverted repeat structure derived from DNA sequence of transformation vector pHoxwG.

Primer KOM32 and nested primer KOM33 as well as primer KOM12 with nested primer KOM13 can target both parts of the inverted repeats but, notably, amplifications using these primer combinations yielded the same sequence structures from five different libraries strongly indicating that the inverted repeat structure extends until the junction of the insert towards assumed potato chromosomal DNA. Furthermore, all fragments isolated contained the same DNA sequence flanking the insert. This established that two truncated T-DNA fragments of different lengths were

fused tail-to-tail thus forming an inverted repeat. Furthermore amplification of flanking sequence yielded the same DNA sequence of all fragments isolated from the GenomeWalker™ libraries indicating that the inverted repeat structure extended into potato chromosomal DNA. Only T-DNA sequence was found in the insert. The structure of the insert of potato event EH92-527-1 including flanking DNA sequence is shown in *Figure 3*. Primers used for the amplification of fragments from GenomeWalker™ libraries are also shown in *Figure 3*.

Southern Blot analysis

Southern blot analysis was also used to investigate the structure of the insert. Preliminary Southern blot experiments consistently yielded one extra band when analyzing potato line EH92-527-1 in comparison with its parental variety Prevalent independent of probe used (data not shown). However from the DNA sequence of the insert derived from amplified fragments an asymmetrically located *EcoRI* site was found (*Figure 3*) that when utilized in combination with other restriction enzymes distinguished between the two repeats of the inverted repeat structure. Results of Southern blot experiments as shown in *Figures 4A to D* are summarized in *Table 1*.

Genomic DNA of EH92-527-1 and its parental variety Prevalent was digested with a number of restriction enzymes, *EcoRI*, *EcoRV*, *HindIII*, *BspHI*, and *MfeI*, in single reactions or in different combinations of the enzymes. All enzymes except *MfeI* cut within the T-DNA (*Figure 4A*) and within the determined structure of the insert (*Figure 3*). The next distal cut site would then be located in the plant genome. The distance to the genomic restriction enzyme site depended on the integration site of the insert. *Figure 5 A to D* show results from Southern blots of different restriction enzyme digests of parental variety Prevalent and potato event EH92-527-1 probed with the different probes representing different portions of pHoxwG T-DNA shown in *Figure 4B*. *Figure 5A* shows results from probing *EcoRI* and *EcoRI-HindIII* digested genomic DNA with a fragment corresponding to the *gbss* promoter. In the *EcoRI* digest one extra band was visualized in EH92-527-1 in comparison to Prevalent.¹ The size of the migrating band was in a region where separation is difficult to obtain and to clearly distinguish whether there is one band or two or more bands with similar migration. In the *EcoRI-HindIII* digest two extra bands corresponding to approximately 3000 bp and 1700 bp could be visualized. This result is consistent with the determined structure of the insert as shown in *Figure 3*, where the predicted results of the Southern blot would yield two bands corresponding to 2801 bp and 1723 bp, respectively. Using the *gbss* promoter as a probe also yielded signals in parental variety Prevalent with corresponding signals detected in EH92-527-1 due to the potato origin of the *gbss* promoter. The two lower bands of approximately 1300 bp, visible in both EH92-527-1 and Prevalent of the *EcoRI-HindIII* digest, correspond to endogenous alleles of the *gbss* promoter, which can yield fragments from 1200 to 1350 bp depending on allelic variation.

Figure 5B shows results from probing *EcoRV* digested genomic DNA with a fragment corresponding to the *nptII* gene. In the *EcoRV* digestion one band corresponding to approximately 3500 bp could be detected in EH92-527-1, which was not detected in Prevalent. This result is consistent with the determined structure of the insert as

¹ Annex B as an amendment to this report clarifies an apparent discrepancy of the Southern blot analysis presented here as compared to previously submitted data in Notification C/SE/96/3501 according to Directive 90/220/EEC.

shown in *Figure 3*, where the predicted results of the Southern blot would yield two bands both corresponding to 3511 bp.

Figure 5C shows results from probing *EcoRI-BspHI* and *EcoRI-MfeI* digested genomic DNA with a fragment corresponding to the *nos* promoter. In the *EcoRI-BspHI* and *EcoRI-MfeI* digestions two bands in each digest could be detected in EH92-527-1, which were not detected in Prevalent. This result is consistent with the structure of the insert as shown in *Figure 3*, where the predicted results of the Southern blot of the *EcoRI-BspHI* digest would yield two bands corresponding to 4152 bp and 5140 bp and is furthermore consistent with the predicted results for the *EcoRI-MfeI* digest, which would yield two bands corresponding to 4306 bp and 5294 bp. *BspHI* would, according to *Figure 3*, digest the genomic DNA of EH92-527-1 at the distal ends of the insert while *MfeI* would digest the genomic DNA of EH92-527-1 in the flanking region outside the distal ends of the insert.

Figure 5D shows results from probing *EcoRI*, *EcoRI-MfeI*, *EcoRI-BspHI* and *EcoRV* digested genomic DNA with a fragment corresponding to the *nptII* gene. These results confirm the results shown in *Figure 5B* and *Figure 5C*. Furthermore, the band seen for the *EcoRV* digest in *Figure 5D* yielded a stronger signal than other bands obtained from the Southern blot which provides evidence that the two expected fragments in the *EcoRV* digest co-migrated. This result is consistent with the structure shown in *Figure 3* with the same flanking sequence being present on both sides of the insert in potato event EH92-527-1.

Results of Southern blot experiments as shown in *Figures 5A* to *D* are summarized in *Table 1*.

Determination of insert and flanking DNA sequence

DNA sequence was assembled from DNA sequence determinations of fragments amplified from GenomeWalker™ libraries using primers, as shown in *Figure 3* and amplicons from PCR reactions using insert locus specific primers as shown in *Figure 1*. Multiple DNA sequence reactions covering all regions were conducted to reduce any potential errors caused by the DNA polymerase during the amplification reactions.

The flanking region was amplified in three independent PCR reactions using primers L1.2F and L1.3R. Cloned fragments (2453 bp) of the three independent reactions were subjected to DNA sequencing. The resulting DNA sequence is shown in *Figure 7*.

The insert was amplified as two overlapping fragments in three independent PCR reactions for each fragment by using primers KOM56R-KOM55R and KOM56F-KOM56R in a first reaction and KOM56RN-KOM55RN and KOM56FN-KOM56RN in a nested reaction. Primer annealing targets are shown in *Figure 6*. The use of these primers produce overlapping PCR fragments where KOM56R anneal to both flanking regions and primers KOM55R and KOM56F anneal to a DNA sequence of the *gbss* antisense fragment in the center of the insert that is not contained in the inverted repeat. Thus each reaction was specific and uniquely targeted one half of the inverted repeat structure of the insert in EH92-527-1 which further verifies the structure as shown in *Figure 3* and *Figure 6*. Three independent KOM56RN-KOM55RN

fragments and three independent KOM56FN-KOM56RN fragments were fully sequenced to allow the determination of a consensus sequence for the insert of EH92-527-1, sequence alignments are shown in *Figure 8* and *Figure 9* respectively. The consensus sequences corresponding to the KOM56RN-KOM55RN fragment and the KOM56FN-KOM56RN fragment were assembled and aligned to a predicted DNA sequence derived from T-DNA sequence of transformation vector pHoxwG, which is shown in *Figure 10*. The determined insert DNA sequence was found to be completely consistent with DNA sequence derived from the T-DNA sequence of transformation vector pHoxwG with no DNA base deviations.

Consensus DNA sequences were used to assemble the complete DNA sequence of the insert structure that is shown in *Figure 11* including the flanking DNA sequence ending at the *EcoRV* site known to be present by Southern blotting analysis (see *Figure 5B* and *Figure 5D*) thus the presented flanking sequence is shorter in *Figure 11* (2156bp) as compared to *Figure 7* (2386 bp).

Stability of insert

Southern blot analysis was used to determine the stability of the insert structure over time where the asymmetrically located *EcoRI* site was utilized alone or in combination with other restriction sites to provide different degrees of resolution and fragment sizes for probe hybridization. Additionally the determined *EcoRV* site in the insert flanking region was utilized. Genomic DNA of EH92-527-1 isolated in 1998 and 2005 was digested with restriction enzyme *EcoRI*, *EcoRV* and combinations *EcoRI-BspHI*, *EcoRI-MfeI*. The results of genomic DNA restriction digested as above and probed with a fragment corresponding to the *nptII* gene are shown in *Figure 12*. The hybridization pattern and thereby restriction pattern is consistent between the DNA isolated in 1998 and 2005 which provides evidence that no structural rearrangements have occurred over this time in the region of investigation and thus the context of the insert is stable.

Conclusions

All presented data are consistent with an inverted repeat structure in the insert of amylopectin potato clone EH92-527-1 extending into potato chromosomal DNA. Southern blot analyses provided complementary evidence for the insert organization suggested by the PCR and the chromosome walking results up to an *EcoRV* restriction site distal to the insert. 2156 bp of insert flanking DNA sequence up to the *EcoRV* restriction site was determined and is presented. No DNA base deviations were found in the insert region as compared to DNA sequence derived from the T-DNA sequence of transformation vector pHoxwG. All inserted DNA sequence was found to be of T-DNA origin and no other DNA was found interspersed among the inserted DNA.

Genomic DNA isolated in 1998 and 2005 was restriction digested and subjected to Southern blot analysis resulting in the same hybridization pattern over four different restriction enzyme combinations providing evidence for genetic stability of the insert over multiple generations of clonally propagated EH92-527-1 in the intervening seven years.

The right borders of the tail-to-tail inverted repeat structure of the insert are truncated, with the complete right border repeat and two further bases deleted. This junction is consistent with right border junctions that are suggested as repair of double-strand breaks (DSB) (Kumar & Fladung 2002). Repair of DSB in plants is commonly achieved by non-homologous end joining that recognize and align microhomologies between different strands of DNA (Gorbunova & Levy 1999). The inverted repeat structure of the insert is starting exactly at such an observed microhomology. DNA repair synthesis utilizing the microhomology on the *gbss* antisense fragment would explain the inverted repeat structure of the insert. DSBs have furthermore recently been suggested to be a major pathway for T-DNA integration in plants (Tzfira et al. 2004).

A. *EcoRI* and *EcoRI-HindIII* digested total DNA of EH92-527-1 and Prevalent hybridized with a fragment corresponding to the *gbss* promoter. B. *EcoRV* digested total DNA of EH92-527-1 and Prevalent hybridized with a fragment corresponding to the *nptII* gene. C. *BspHI-EcoRI* and *MfeI-EcoRI* digested total DNA of EH92-527-1 and Prevalent hybridized with a fragment corresponding to the *nos* promoter. D. *EcoRI*, *EcoRI-MfeI*, *EcoRI-BspHI* and *EcoRV* and digested total DNA of EH92-527-1 and Prevalent hybridized with a fragment corresponding to the *nptII* gene. P, Prevalent; K, positive control; M, marker; bp, base pair.

Figure 6. Structure of insert locus with primers used for amplification of specific fragments for verification of flanking DNA sequence, insert structure and complementary sequencing.

EcoRV

Figure 9. DNA sequence alignment of three independently amplified fragments from reactions with primers KOM56FN and KOM56RN. A consensus sequence is derived from the alignment in view of errors introduced by the DNA polymerase.

Figure 10. DNA sequence alignment of the insert consensus DNA sequence with DNA sequence assembled from T-DNA sequence of transformation vector pHoxwG. The insert consensus DNA sequence was assembled from consensus DNA sequence of fragments from reactions with primers KOM56RN-KOM56FN and KOM56FN- KOM56RN.

Figure 11. Determined DNA sequence of insert and flanking potato chromosomal DNA of potato line EH-92-527-1. Potato chromosomal DNA is shown in bold.

FIGURE 12. Southern blot analysis for determination of insert stability in EH92-527-1. 10µg total DNA from EH92-527-1 isolated in 1998 and 2005 was digested with various restriction enzymes and hybridized with a fragment corresponding to the *nptII* gene. K, positive control; M, marker; bp, base pair.

ANNEX A

Description of Amendments to the Report

The report was amended to add additional pertinent information including several figures containing sequence data, an additional Southern blot examining insert stability and corrections to the text.

Specific amendments to the report are as follows:

Page 2. Annexes A and B are new

Page 3. Figure 8. is now Figure 11. There is a new Figure 8. and Figures 9, 10 and 12 are new.

Page 4. Last paragraph of Summary is new.

Page 5. An additional DNA isolation method is included under DNA isolation.

Page 9. Under Southern Blot analysis, second paragraph the footnote is new.

Page 10. Under Determination of insert and flanking DNA sequence, third paragraph is amended.

Page 11. First paragraph is amended.

Page 11. Second paragraph is amended.

Page 11. Paragraph on Stability of insert is new.

Page 11. Under Conclusions, first paragraph is amended

Page 11. Under Conclusions, second paragraph is new.

Page 12. Haymes (1996) reference is new.

Figure 8 in the original report is now Figure 11.

Figure 8 is new.

Figure 9 is new.

Figure 10 is new.

Figure 12 is new.

ANNEX B

Amended Southern blot description

Notification C/SE/96/3501 submitted according to Directive 90/220/EEC included Annex 4 entitled “Southern blotting for determination of the number of gene copies incorporated in EH92-527-1” by Mariette Andersson. In this report a Southern blot analysis on an *EcoRI* digest of genomic DNA from both EH92-527-1 and the parental variety Prevalent was presented, hybridized with a probe targeting the *gbss* promoter. This blot was apparently inconsistent with a Southern blot analysis submitted as part of Notification C/SE/96/3501 Update according to Directive 2001/18/EC. Further investigation revealed that the autoradiogram used for original submission was inadvertently flipped and therefore a *HindIII* digest was mislabeled as an *EcoRI* digest. The Southern blot presented in the original submission is now labelled correctly and shown as *Figure 1* of this *Annex B*. The Southern blot analysis was performed in May of 1996 before the complete DNA sequence of the insert was known.

The complete DNA sequence, structure of the insert and flanking DNA sequence is now known permitting a comprehensive interpretation of the original Southern blot analysis. The probe targeting the *gbss* promoter will also hybridize with fragments separated in the digests of the parental variety Prevalent as the DNA segment used as probe is of potato origin. As can be seen from the known structure of the insert of EH92-527-1, *Figure 2*, a *HindIII* digest will yield one internal fragment from the insert region. This fragment represents 4434 bp of the insert and has two target sites for the *gbss* promoter probe. In *Figure 1*, hybridization to this fragment is indicated as A. In the original submission this band is indicated as representing a fragment size above 2027 bp and below 6557 bp, which is consistent with the determined structure of the insert in EH92-527-1. Hybridization to the *EcoRI* digest also results in one extra band as can be seen in *Figure 1* and which is indicated as B. As can be seen in *Figure 2*, the insert of EH92-527-1 contains one *EcoRI* restriction site and would upon digestion yield two separate fragments with one target site each for the probe used. In the main report an autoradiogram is shown that represents *EcoRI* digests of genomic DNA from EH92-527-1 isolated in 1998 and 2005. Both these hybridization patterns show two bands using a probe targeting the *nptII* gene. The bands seen in this Southern blot are represented by bands indicated as B and C in *Figure 1*, where C is superimposed on a band which is also present in the parental variety Prevalent.

Thus the Southern blot from the original submission is consistent with the known DNA sequence and structure of the insert in EH92-527-1 presented in the main report but was incorrectly labeled as an *EcoRI* digest in the original submission.

Figure 1. Southern blot analysis for determination of T-DNA insertions in EH92-527-1 produced in May of 1996. 10µg total DNA from EH92-527-1 and the parental variety Prevalent was digested with *HindIII* or *EcoRI* and hybridized with a fragment corresponding to the *gbss* promoter. A indicates a band of the *HindIII* digest, which is the result of an insert internal fragment with two probe target sites, B indicates a band of the *EcoRI* digest, C indicates a band of the *EcoRI* digest, which is superimposed on a fragment also detected in parental variety Prevalent. P, Prevalent; K, positive control; M, marker.

Figure 2. Determined structure of genetic insert (9378 bp) and flanking sequences of EH92-527-1. DNA segments outside the p-nos elements is 2156 bp potato chromosomal flanking DNA on each side of the insert. Structural components noted, p-nos-nopaline synthase promoter, nptII -coding sequence for aminoglycoside phosphotransferase II, t-nos-nopaline synthase polyadenylation sequence, p-gbss-potato gbss promoter, s-gbss-truncated gbss antisense fragment, as-gbss-truncated gbss antisense fragment.
